

"Turning effect of a force also called moment of a force"

Definition:

Product of forces and the perpendicular distance between the force and the pivot.

Ex 1.

$$\begin{aligned}\text{Moment} &= F \times d \\ &= 4 \times 20 \\ &= 80 \text{ N}\end{aligned}$$

Ex 2

$$\begin{aligned}\text{Moment} &= 0 \text{ N} \\ &\text{because perpendicular distance} \\ &\text{is } 0.\end{aligned}$$

Ex 3

Method 1: Resolve the force and calculate moment with the component perpendicular to the distance from the pivot.

$$\begin{aligned}\text{Moment} &= F \times d \\ &= 10 \sin 60 \times 8 \\ &= 80 \sin 60 \\ &= 69 \text{ Nm}\end{aligned}$$

Method 2: Extend the line of action of the force and calculate shortest distance between the extended line and the pivot.

$$\begin{aligned}\sin 60 &= \frac{d}{8} \\ 8 \sin 60 &= d\end{aligned}$$

$$\begin{aligned}\text{Moment} &= F \times d \\ &= 10 \times 8 \sin 60 \\ &= 80 \sin 60 \\ &= 69 \text{ Nm}\end{aligned}$$

What are the conditions of equilibrium?

1. Turning effect must be 0, that is, clockwise moments must equal upwards force
2. Resultant force must also be 0.

Graph of F vs. d , keeping moment constant

$$F \propto \frac{1}{d} \text{ (Inversely proportional)}$$

Q.

Apply principle of moments taking P as a pivot to form an equation given that the rod is in equilibrium.

$$\begin{aligned} \text{CWM} &= F_1 \times y \\ \text{CCWM} &= F_2 \times x \end{aligned}$$

$$\text{Final equation} \Rightarrow (F_1)(y) = (F_2)(x)$$

How to find the resultant moments?

- Concept of resultant moments will only arise if one turning effect, either clockwise or counter clockwise, is greater / lesser than the other turning effect.

Example:

Calculate the resultant turning effect.

A. $ACW = 5 \times 5 = 25 Nm$

B. $ACW = 10 \times 5 = 50 Nm$

C. $CW = 20 \times 2 = 40 Nm$

$$\begin{matrix} ACW & CW \\ [25 + 50] & - [40] = \text{Resultant} \end{matrix}$$

$$75 - 40 = 35 \text{ ACW}$$

\therefore , the resultant turning effect is 35 Nm anticlockwise

Concept of turning effect of a "couple" also called torque of a "couple":

Couple: refers to two equal and anti-parallel forces acting on the object at different points.
 having opposite directions

Example:

Torque of a couple: Any one force multiplied by the perpendicular distance between the two forces.

Example:

$$\sin 40 = \frac{d}{10}$$

$$10 \sin 40 = d$$
